

## General Patterns in Evolution

---

---

---

---

---

---

---

---

## Uses of Phylogenetic Analysis

- Allows mapping order of character state changes
- Documents evolutionary trends in development
- Reveals that Homoplasy is common
- Can attempt to equate timing with fossil record events

---

---

---

---

---

---

---

---

---

Tracing the path of evolution to *Homo sapiens* from the universal ancestor of all life

1. Origin of eukaryotes: a symbiotic bacterium becomes the mitochondrion.
2. Multicellularity evolves: cell and tissue differentiation.
3. Animals: internal digestive cavity develops.
4. Dinosaurian ancestors: bladders develop into arms.
5. Chordates: notochord, dorsal nerve cord.
6. Mammals: hair, dentition.
7. Simioids: legs.
8. Amniotes: amniotic egg, other water conserving features.
9. Mammals: unique jaw joints, middle ear bones, milk.
10. Primates: binocular vision, adaptability.
11. Anthropoid apes: loss of tail.
12. Hominins: evolve bipedality.
13. Homo sapiens: spreads from Africa.

Phylogenies Reveal that Homoplasy is Common

• **Convergent** and **parallel** evolution - the independent gain of a trait

---

---

---

---

---

---

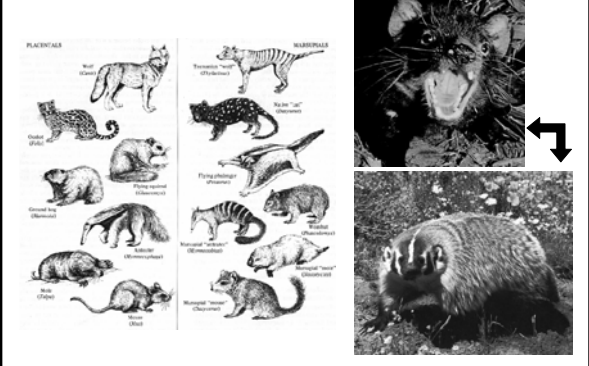

---

---

---

---

### Convergent Evolution among Placental Mammals and Marsupials

---

---

---

---

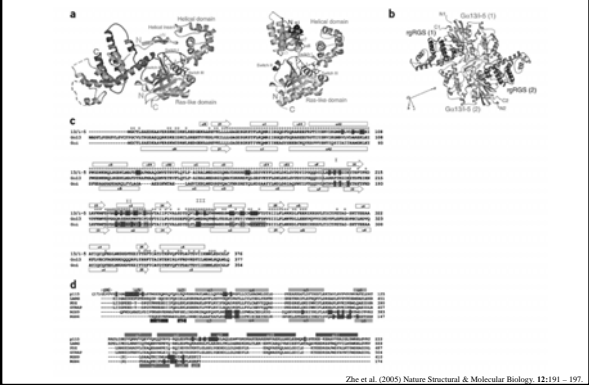

---

---

---

---

### Structure of the p115RhoGEF rgRGS domain- $\alpha$ 13/11 chimera complex suggests convergent evolution of a GTPase activator.

Zhe et al. (2005) Nature Structural & Molecular Biology, 12:191-197

---

---

---

---

---

---

---

---

### Parallel evolution: Special case of Convergent evolution

Feeding structures (maxillipeds) from thoracic legs in crustaceans.

## The Evolution of Traits aka phenotypes

Linear interactions

Non-linear interactions

---

---

---

---

---

---

---

---

---

---

---

---

Polymorphic mimicry in *Papilio dardanus* (The mocker swallowtail): accurate mimics of different species of distasteful butterflies.

Single Locus; ~11 mimicking alleles that are more variable.

---

---

---

---

---

---

---

---

---

---

---

---

Biological traits come about through developmental processes and physiological regulatory mechanisms. Most of these processes are nonlinear. Examples of nonlinear processes are:

- The sensitivity of reaction rate to substrate concentration
- inhibition
- negative feedback
- positive feedback
- cooperativity
- most non-steady state processes
- any process that depends on diffusion

Any mechanism that contains one or more of these processes (and most regulatory mechanisms in biology do) will have a nonlinear relationship between variation in its determinants and variation in the trait affected by the process.

**Rates of Evolution Vary Among Lineages**

---

---

---

---

---

---

---

---

**Rates of Evolution Vary Among Characters**

Evolution of different characters at different rates within a lineage:  
**Mosaic Evolution**

Combines concepts of **Gradualism vs. Saltation**

---

---

---

---

---

---

---

---

Inferred pairwise nucleotide substitutions among 17 mammal species from seven gene products, as estimated from protein studies, plotted against date of divergence, as estimated from the fossil record. The line is drawn from the origin through the oldest point (marsupial/placental divergence at 125 MYA). The strong linear relationship suggests that **molecular differences between pairs of species are proportional to the time of their separation**, rather than the degree of organismal difference. Therefore, measures of genetic divergence can be used to date the time of divergence for species pairs for which no fossil data are available: genes function as **Molecular Clocks**. (from A. C. Wilson 1976)

## Adaptive Radiation is Widespread aka Divergent Evolution

Hawaiian Honeycreepers

The phylogenetic tree shows the following species and their adaptations:

- Scolecophagus*: Laysan Finch (Fruit and seed eater)
- Chrysomitris*: Akaka (Small prey)
- Myzomela*: Hawaii Amakihi (Nectar feeder and generalist)
- M. parva*: Amakihi (Nectar feeder and generalist)
- Lanius*: Amakihi (Small prey)
- L. lucidus*: Amakihi (Small prey)
- Melospiza*: Lani (Nectar feeder and generalist)
- Psaltriparus*: Amakihi (Nectar feeder and generalist)
- Psaltriparus*: Amakihi (Nectar feeder and generalist)

---

---

---

---

---

---

---

---

---

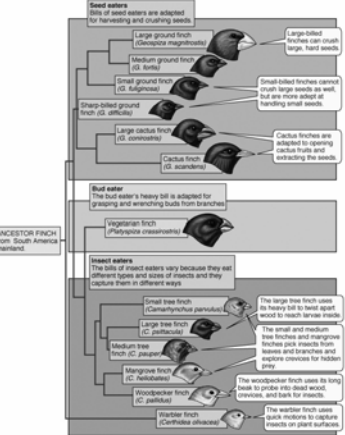

---

## Adaptive Radiation is Widespread

Darwin's Finches are the classic example.

The tree illustrates the following adaptations:

- Seed eaters**: Bills of seed eaters are adapted for harvesting and crushing seeds.
  - Large ground finch (*Geospiza magnirostris*): Large billed - feeds on large, hard seeds.
  - Medium ground finch (*G. fortis*): Small billed finches cannot crush large seeds as well, but are more adept at handling small seeds.
  - Small ground finch (*G. pusilla*): Small billed finches cannot crush large seeds as well, but are more adept at handling small seeds.
- Insect eaters**: The bird eater's hairy bill is adapted for grasping and wrenching buds from branches.
  - Vegetarian finch (*Phoenicurus*): Cactus finches are adapted to sparring cactus buds and extracting the seeds.
  - Large cactus finch (*G. stricklandi*): Cactus finches are adapted to sparring cactus buds and extracting the seeds.
  - Cactus finch (*G. scandens*): Cactus finches are adapted to sparring cactus buds and extracting the seeds.
- Insect eaters**: The bills of insect eaters vary because they eat different sizes and sizes of insects and they capture them in different ways.
  - Small tree finch (*Camarhynchus parvulus*): The large tree finch uses its heavy bill to feed against wood to reach larvae inside.
  - Large tree finch (*C. pallasi*): The small and medium tree finches and mangrove finches and mangrove finches and mangrove finches use their bills to pry open crevices for hidden prey.
  - Medium tree finch (*C. parvulus*): The woodpecker finch uses its long beak to probe into dead wood, crevices, and bark for insects.
  - Mangrove finch (*C. melanotos*): The mangrove finch uses quick motions to capture insects on plant surfaces.
  - Woodpecker finch (*C. pallasi*): The woodpecker finch uses its long beak to probe into dead wood, crevices, and bark for insects.
  - Warbler finch (*C. melanocephalus*): The warbler finch uses quick motions to capture insects on plant surfaces.

## Adaptive Radiation is Widespread

Lake Malawi Cichlids (>500 spp.)

---

---

---

---

---

---

---

---

---

---

---

---

## Coevolution

FIGURE 4.10 Fluctuations in abundance of lynx and hare in northern Canada based on numbers of furs purchased by the Hudson Bay Company. The cause of the complex cycles are still unclear. (After Purves et al. 2006.)

- Predators and their prey.
- Parasites and their hosts.
- Plant-eating animals and the plants upon which they feed.
- Coevolution is the joint change of two or more species in close interaction.
- Plants and the animals that pollinate them.

---

---

---

---

---

---

---

---

---

---

---

---

## Modification of Preexisting Features

Figure 3.11 Variation in mollusc eyes (a) A pigment spot; (b) a simple pigment cup; (c) the simple optic cup found in abalone; (d) the complex lensed eyes of a marine snail called *Littorina* and the octopus. Pigmented cells are shown in color.
